Appendix G

Appendix G Air Quality

An emissions analysis was conducted to develop emissions inventories pursuant to the National Environmental Policy Act of 1969 (NEPA), and to determine whether emissions associated with the Proposed Action would exceed applicable *de minimis* thresholds as documented in the U.S. Environmental Protection Agency's (EPA's) general conformity regulations.

This appendix documents the methods used to calculate emissions of U.S. EPA criteria pollutants, including carbon monoxide (CO), volatile organic compounds (VOCs), oxides of nitrogen (NO_X), oxides of sulfur (SO_X), particulate matter less than ten microns in diameter (PM_{10}), and particulate matter less than 2.5 microns in diameter ($PM_{2.5}$), from operational and construction-related sources of emissions associated with the Proposed Action Alternative. In addition, the methodologies used to calculate operational and construction-related emissions of greenhouse gases (GHGs)¹ and hazardous air pollutants (HAPs) are presented in this appendix.

Operational emissions inventories were developed for existing conditions (2012) and for two future years (2015 and 2020). Future year emission inventories were developed for the No Action and Proposed Action Alternatives evaluated in this environmental assessment.

Estimates of construction-related emissions were developed for the Proposed Action Alternative using standard industry methodologies and techniques. All construction activities are anticipated to be completed in 2015; hence construction emissions estimates were developed for calendar year 2015.

G.1 Construction Emissions Analysis

This section documents the analysis of estimated emissions generated through construction-related activities associated with constructing the Proposed Action Alternative. Major components of the Proposed Action Alternative included in the construction emissions analysis include pavement rehabilitation of a portion of Runway 24R's keel (or center) section, pavement rehabilitation of Taxiway AA, constructing a cover for a portion of the Argo Drainage Channel located north of the Runway 24R threshold, and demolition and relocation of various service roads.

¹ For purposes of this analysis, greenhouse gas emissions are estimated in terms of carbon dioxide equivalent (CO2e).

Construction emissions analyses generally require information such as the type of construction equipment to be used, the amount of time the equipment will operate, estimates of required construction material, areas to be paved, and the number of employees anticipated to be on site. A construction schedule and estimate of various material quantities were provided by URS Corporation. Construction activity estimates, including types, number, and specifications of equipment for various construction activities, were derived from data provided by MARRS Services, Inc., in support of the LAX Runway 7L/25R RSA EA.² This data included various types and numbers of construction equipment organized into crews. Crews were assigned to specific construction activities associated with the Proposed Action Alternative by identifying activities that are similar in nature to activities included in the LAX Runway 7L/25R RSA EA. Estimates of construction-related emissions were developed for the Proposed Action Alternative using standard industry methodologies and techniques. Activities associated with construction of the Proposed Action are anticipated to begin in July 2015 and to be completed in December 2015.

Sources of construction emissions estimated in this analysis included construction vehicles and equipment, pavement crushing, asphalt paving and pavement painting activities.³ Construction equipment emissions are generally estimated using two basic methodologies (nonroad and on-road) depending on the type of construction equipment. Nonroad construction equipment (e.g., bulldozers, backhoes, front end loaders) are generally operated off road and on the construction site. On-road construction equipment (e.g., semi-trucks for material hauling), in contrast, can be operated on public roads. Emissions for on-road construction equipment and nonroad construction equipment were estimated separately, following standard industry practices.

G.1.1 NONROAD CONSTRUCTION EQUIPMENT

Nonroad construction equipment includes dozers, loaders, sweepers, and other heavy-duty construction equipment that operates on the construction site, but is not licensed to travel on public roadways. Nonroad equipment emissions were calculated as shown in **Equation G-1**.

Nonroad equipment types, models, horsepower, and load factor were assigned to each construction task for the Proposed Action Alternative, as previously described. Equipment operating times were derived assuming a 10-hour-per-day, 6-day-per-week workweek. To account for equipment downtime throughout the day, an equipment-specific efficiency factor was calculated from data obtained from the California Air Resources Board (CARB) OFFROAD2007 emission factor model, consistent with the methodology used in the LAX Runway 7L/25R RSA EA.

² City of Los Angeles, Los Angeles World Airports, *Final Environmental Assessment for Los Angeles International Airport (LAX) Runway 7L/25R Runway Safety Area (RSA) and Associated Improvements Project*, August 2013.

³ It was assumed that asphalt would be batched offsite at batch plant facilities operating under stationary source permits and therefore, emissions were not estimated separately for batch plants.

Equation G-1 Nonroad Construction Equipment Emissions Calculation Equation

$E = HP \times L \times H \times e \times EF$

Where:

| E | = | emissions (lb/day) |
|----|---|--|
| HP | = | horsepower |
| L | = | load factor |
| н | = | total hours per day of equipment operation |
| е | = | efficiency factor |
| EF | = | emission factor (lb/hp-hr) |
| | | ociates, Inc., January 2014. ४ Associates, Inc., February 2014. |

Emission factors for nonroad equipment were obtained from several sources. For CO and SO_x, emission factors were obtained from CARB's OFFROAD2007 emission factor model for 2015. For each construction equipment type, the model generates emissions in tons per day for several horsepower ranges/bins. For each equipment type and horsepower bin combination, the emissions in tons per day were multiplied by 2000 (pounds per ton) and divided by activity (hours per day), load factor (from the OFFROAD2007 data file), and average horsepower (from the OFFROAD2007 data file). Using this methodology, an emission factor in pounds per horsepower-hour (lb/hp-hr) was derived for each equipment type by horsepower bin. The emission factor applied to a given piece of equipment was then selected based on the horsepower of the equipment. It should be noted that the OFFROAD2007 model does not include every specific type of equipment assumed for construction of the Proposed Action Alternative. Where necessary, specific equipment types were matched with an equivalent/representative OFFROAD2007 equipment type for purposes of selecting an appropriate emission factor.

Emission factors for VOC, NO_X, and PM₁₀ were obtained and used based on construction-related air quality control measures developed for LAX. All off-road diesel-powered construction equipment greater than 50 horsepower was assumed to meet USEPA Tier 4 off-road emission standards for these pollutants (final Tier 4 NO_X standards were assumed for most equipment types, based on assumptions used in the LAX Runway 7L/25R RSA EA). These emissions standards are reflected in emission factors reported in grams per horsepower-hour (g/hp-hr) for various horsepower ranges. The factors were converted to lb/hp-hr for emissions calculation purposes.

CARB's OFFROAD2011 emission factor model was used for deriving emission factors of VOC, NO_X, and PM₁₀ for off-road construction equipment less than 50 horsepower. The computation of emission factors from OFFROAD2011 was performed essentially identically to the methodology described previously for deriving emission factors from OFFROAD2007.

 $PM_{2.5}$ emission factors were derived using the PM_{10} emission factors and $PM_{2.5}$ size profiles derived from the CARB-approved California Emission Inventory Development and Reporting System (CEIDARS) database. In this case, a factor of 0.92 was applied to PM_{10} emission factors to derive $PM_{2.5}$ emission factors. This factor represents the size fraction of PM_{10} emissions that can be assumed to be $PM_{2.5}$ emissions with respect to diesel vehicle exhaust.

The data used to estimate emissions from nonroad construction equipment in 2015, as well as total emissions by equipment type, are presented in **Table G-1**.

G.1.2 ON-ROAD ON-SITE CONSTRUCTION EQUIPMENT

On-road on-site equipment emissions are generated from on-site pickup trucks, water trucks, haul trucks, cement trucks, flatbed trucks, and other trucks that are licensed to travel on public roadways. **Equation G-2** was used to calculate emissions from on-road on-site equipment.

Equation G-2 On-Road Construction Equipment Emissions Calculation Equation

$E = VMT \times EF$

Where:

| Ε | = | emissions (lb/day) |
|-----|---|--------------------------------|
| VMT | = | vehicle miles traveled per day |
| EF | = | emission factor (lb/mile) |

SOURCE: Ricondo & Associates, Inc., January 2014. PREPARED BY: Ricondo & Associates, Inc., February 2014.

Equipment types and specifications by construction activity for on-road on-site equipment were developed in the same way as nonroad equipment. Emissions factors for all criteria pollutants (including PM_{2.5}) for on-road on-site equipment were obtained from CARB's EMFAC2011 emission factor model. The EMFAC2011 model was run for 2015 and each seasonal period (annual, summer, winter) in the South Coast Air Basin.

Notes:

Columns may not add to totals shown because of rounding.

1/ Vehicle emissions are calculated by multiplying the annual hours, load factor, horsepower, emission factor, usage factor, and conversion factor (1 ton/2000 pounds = 0.0005) to create a value of tons per year for each piece of equipment.

2/ PM₁₀ and PM_{2.5} emissions include fugitive dust.

EMISSIONS (TONS PER YEAR) ^{1/}

THIS PAGE INTENTIONALLY LEFT BLANK

EMFAC2011 contains a comprehensive list of vehicle categories. For this analysis, on-site pickup trucks were assumed to be represented by the LHD2 (gasoline) EMFAC2011 vehicle category, which is defined as light-heavy-duty trucks (10,001-140,000 lbs.). All other on-road on-site equipment was assumed to be represented by the T7 single construction (diesel) EMFAC2011 vehicle category. This category is defined as heavy-heavy duty diesel single unit construction trucks. In accordance with construction-related air quality control measures developed for LAX, emission factors for these vehicles were modeled for model year 2007 vehicles to represent compliance with U.S. EPA 2007 on-road emissions standards.

For diesel vehicles, the EMFAC2011 factors account for running and idling emissions for all pollutants. PM₁₀ and PM_{2.5} factors include tire and brake wear. For gasoline vehicles, VOC emission factors include diurnal, hot soak, running, and resting emissions, and the PM₁₀ and PM_{2.5} factors include tire and brake wear. EMFAC2011 emission factors are expressed in pounds per mile; therefore, roundtrip distances for on-site travel were determined for each vehicle type to calculate emissions in pounds per day. Travel distances were assumed to be 5 miles roundtrip for water trucks and sweepers, and 2 miles roundtrip for all other vehicles. In addition, on-road on-site vehicles were assumed to travel at a speed of 20 mph. These assumptions are consistent with the LAX Runway 7L/25R RSA EA.

In accordance with construction-related air quality control measures developed for LAX, diesel vehicles (in this case the T7 single construction vehicles) were assumed to be fitted with exhaust retrofit devices providing an 85-percent reduction in PM₁₀ and PM_{2.5} emissions.

Table G-2 presents the EMFAC2011 emission factors used to calculate emissions for on-road on-site construction equipment for the Proposed Action Alternative for 2015. The emission factor for fugitive dust accounts for emissions of fugitive dust particulate matter entrained by vehicular travel on paved roads.

G.1.3 ON-ROAD OFF-SITE CONSTRUCTION EQUIPMENT

On-road off-site trips include personal vehicles used by construction workers to access the construction site, as well as hauling trips for the transport of various materials to and from the site. The emissions calculation is the same as the calculation of on-site on-road vehicles.

Emission factors for on-road off-site vehicles were obtained from EMFAC2011 in the same way as described previously for on-road on-site vehicles, although emission factors were used in units of g/mi and applied to the VMT estimates to calculate total emissions. For all on-road off-site vehicles, emission factors were obtained assuming an aggregated speed. **Table G-4** presents the EMFAC2011 emission factors used to calculate emissions for on-road off-site construction equipment for the Proposed Action Alternative for 2015.

| | | EMISSION | I FACTORS (G | RAMS/VEHICL | E-MILE) 1/ | | FUGITIV | E DUST ^{2/} |

2/ Fugitive dust emission factor measured in grams/vehicle-mile and derived from U.S. Environmental Protection Agency, *Compilation of Air Pollutant* Emission Factors AP-42, Volume I: Stationary Point and Area Sources, Chapter 13.2.1, "Paved Roads," updated January 2011.

SOURCE: Ricondo & Associates, Inc., December 2013, based on output from the California Air Resources Board EMFAC2011 emission factor model. PREPARED BY: Ricondo & Associates, Inc., February 2014.

Total daily construction workers for a given construction activity was derived from crew data provided by MARRS Services, Inc. for the LAX Runway 7L/25R RSA EA. Total daily workers were converted to daily vehicle trips by assuming a factor of 1.15 workers per vehicle per trip. Daily VMT for construction worker vehicles was then calculated by multiplying the number of daily vehicle trips by an assumed roundtrip distance of 40 miles. To represent a mix of construction worker vehicles, the analysis assumed a mix of 50 percent passenger cars (EMFAC2011 vehicle category LDA), 30 percent light-duty trucks (0-3,750 lbs.) (LDT1) and 20 percent light duty trucks (3,751-5,750 lbs.) (LDT2). This vehicle mix is identified in the South Coast Air Quality Management District (SCAQMD) California Emissions Estimator Model (CalEEMod) as an option for modeling emissions from construction worker vehicles and represents a reasonable vehicle mix for such trips.

Off-site hauling trips include the delivery of construction materials, concrete, asphalt, and base material to the construction site, and hauling of excess cut/fill material and demolished pavement from the construction site. The calculation of VMT for on-road on-site hauling trips was based on quantities provided by URS Corporation. Haul trucks were assumed to have a capacity of 20 cubic yards, while transit cement mixers were assumed to have a capacity of 10 cubic yards. Based on information from Connico, Inc., haul trucks were assumed to travel a roundtrip distance of 40 miles for all hauling trips, except for concrete deliveries (25 miles) and hauling of demolished pavement (5 miles). For off-site hauling trips, the T-7 single construction EMFAC2011 vehicle category was assumed for all vehicles.

Table G-5 presents emissions estimates for on-road off-site construction equipment for the Proposed Action Alternative.

G.1.4 PAVEMENT CRUSHING

Various elements of the Proposed Action Alternative involve the demolition of existing concrete or asphalt pavement. It was assumed that the demolished pavement would be hauled to an on-site crusher and crushed. The crushing process generates exhaust emissions from the running crusher, as well as fugitive dust. **Table G-6** presents the methodology and results of estimating emissions associated with utilization of the crusher equipment.

PREPARED BY: Ricondo & Associates, Inc., February 2014.

Runway 6L-24R and Runway 6R-24L Runway Safety Area and Associated Improvements EA Appendix G – Air Quality

G.1.5 FUGITIVE DUST

Additional sources of PM_{10} and $PM_{2.5}$ emissions associated with construction activities are related to fugitive dust. Fugitive dust includes re-suspended road dust from both off- and on-road vehicles, as well as dust from grading, loading, unloading, and other activities. Additional sources of fugitive dust quantified in the analysis included building demolition, crushing of demolished pavement, and concrete batching.

Fugitive dust emissions (PM_{10} and $PM_{2.5}$) were calculated using the guidance from the USEPA's AP-42, the SCAQMD's CEQA Air Quality Handbook, and documentation associated with CalEEMod. Fugitive dust emissions were calculated for the following construction activities and incorporated into the nonroad, on-road, and pavement crushing emissions analyses, as appropriate:

- Vehicles traveling on paved roads. All off-site on-road vehicles are assumed to travel on paved roads.
- Vehicles traveling on unpaved roads. All on-road on-site vehicles are assumed to travel on unpaved roads.
- On-site construction activities (grading, crushing, loading, hauling and storage)
- An on-site rock crusher. An overall emission factor was derived by summing emission factors for crushing activities including tertiary crushing, fine crushing, and screening.

Water, as required under LAWA construction contracts and also being one of the main dust suppression measures recognized in SCAQMD Rule 402, was assumed to reduce fugitive dust emissions by 61 percent.

G.1.6 FUGITIVE VOCS

The primary source of construction-related fugitive VOC emissions is hot-mix asphalt paving. VOC emissions from asphalt paving operations result from evaporation of the petroleum distillate solvent, or diluent, used to liquefy asphalt cement. Based on the CARB default data contained within CalEEMod, an emission factor of 2.62 pounds of VOC (from asphalt curing) per acre of asphalt material was used to determine VOC emissions from asphalt paving. VOCs resulting from the application of runway/taxiway striping were also estimated. **Table G-7** presents the VOC emissions associated with asphalt paving and pavement striping/painting.

| ASPHAL | ASPHALT PAVING EMISSIONS | | | | | |
|-------------------------|--------------------------|-------|----------|--|--|--|

PREPARED BY: Ricondo & Associates, Inc., February 2014.

G.1.7 AIRCRAFT OPERATIONS DURING CONSTRUCTION

Runway 6L-24R would be closed for approximately 4 months during the runway rehabilitation construction period; operations from this runway must be accommodated through the use of other runways at LAX during this time. Additionally, operations of ADG IV or greater aircraft would need to shift to other runways during the 2 months of reduced runway length on Runway 6L-24R. In order to determine air quality impacts during this period, airport simulation models (SIMMOD) were developed for the 2015 No Action Alternative and the 2015 runway closure period. Information on the number and types of aircraft operations considered at LAX for 2015 were developed specifically for the Project. These data were used to develop SIMMOD of aircraft operations in order to determine Project-specific taxi/idle times. The SIMMOD used information about facilities and operations to predict specific timing, volume, and location (e.g., runway used) for aircraft operations.

The incremental differences in SIMMOD taxi/idle times were used for the analysis of aircraft emissions associated with the shift in aircraft operations during the runway closure; taxi/idle times during this period will be slightly greater than normal operations during 2015. In addition, to allow for completion of construction work on a portion of the Argo Ditch, Runway 6L-24R must operate at a reduced length of 7,000 feet for a period of 60 days (2 months). Taxi times for this period were calculated using the increased taxiing distance and a taxiway speed of 15 knots. A detailed discussion describing the methodology to the taxi times is found in Section G.2.2, *Aircraft Time in Mode*. A summary of the taxi times are shown in **Table G-8**.

| | Table G-8 Comparison o | f Taxi Times during Runway C | losure |

| | 2015 NO ACTION | 2015 RUNWAY CLOSURE | 2015 SHORTENED RUNWA PERIOD |
| Arrivals | 9.21 | 9.26 | 9.39 |
| Departures | 12.05 | 12.62 | 12.05 |

SOURCE: Ricondo & Associates, Inc., March 2014.

PREPARED BY: Ricondo & Associates, Inc., March 2014.

Operational aircraft emissions for the No Action Alternative and Proposed Action were calculated using the taxi times in Table G-8 and FAA's Emissions and Dispersion Modeling System (EDMS), Version 5.1.4.1. EDMS is a U.S. EPA approved air quality model that estimates emissions from airport sources based on information input into the model. Aircraft emissions occur during approach, taxi-in (from runway to apron including landing roll), engine startup at the apron, taxi-out (from apron to runway), takeoff, and climb-out; emissions for each of these operational modes were calculated for the 2015 No Action Alternative and the 2015 runway closure period. The taxi/idle times were derived from the SIMMOD results. However, as none of the other operational phases would be affected by the runway closure or reduced runway length, the EDMS default times-in-mode were the basis for climbout, approach, and takeoff times; however, climbout and approach times were adjusted according to the average mixing height adjustment parameters contained in EDMS. For LAX, a mixing height of 1,806 feet above mean sea level was used in the emissions modeling.

The aircraft fleet mix and operational levels for the 2015 No Action Alternative and the 2015 runway closure period were assumed equal to the Proposed Action Alternative, as further discussed in section G.2.

Annual emissions outputs from EDMS for the runway closure and reduced runway length periods, and normal operations, were then normalized based on the 4-month runway closure and 2-month reduced runway period.

Hazardous air pollutant (HAPs) and greenhouse gas (GHG) emissions were calculated in a consistent manner with the methodology for operational impacts, as discussed in sections G.2.3 and G.2.4, respectively.

G.1.8 SUMMARY OF CONSTRUCTION EMISSIONS ANALSYIS

A summary of total construction-related emissions for the Proposed Action Alternative in 2015 is presented in **Table G-9**.

| | | | EMISSIONS (| TONS/YEAR) | | |
|---------------------------------|--------|-------|-----------------|------------|-------------------------|-------------------|

SOURCE: Ricondo & Associates, Inc., January 2014.

PREPARED BY: Ricondo & Associates, Inc., February 2014.

G.1.9 HAZARDOUS AIR POLLUTANTS

Hazardous air pollutants (HAPs) are pollutants that do not have established NAAQS, but present potential adverse human health risks from short-term (acute) or long-term (chronic) exposures. Although the analysis of HAPs is not an FAA requirement, the HAPs inventory presented in the EA is for disclosure purposes. HAPs of concern that were included in this analysis were included based on emissions estimates and human toxicity information, as well as results of the *LAX Master Plan Final Environmental Impact Statement/Environmental Impact Report* Human Health Risk Assessment.⁴

Both organic and particulate-bound HAPs were calculated for this EA. HAPs exist in air as either reactive organic gases or particulate matter. For purposes of this EA, organic emissions are represented by volatile organic compounds (VOC). Emission inventories of organic HAPs were developed from VOC emission inventories for the same construction sources as previously outlined. HAPs associated with small particles, or those particles less than 10 microns in diameter (PM₁₀), are the focus for particulate emissions, because this size fraction can deposit in the lung and are therefore primarily responsible for inhalation exposure. Speciation profiles were applied to annual emissions inventories for VOC and PM₁₀ from individual source types.

⁴ City of Los Angeles, Los Angeles World Airports, Los Angeles International Airport Master Plan Final Environmental Impact Statement/Environmental Impact Report, January 2005.

Emissions of DPM (assumed to be equal to the engine exhaust component of particulates less than 10 microns in diameter) are expected to contribute the majority to total incremental cancer risks for construction sources. Based on previous evaluations of construction impacts at LAX, other HAPs have minimal contributions. However, HAPs emissions inventories evaluated the release of DPM as well as other associated HAPs from construction equipment.

HAPs inventories for construction equipment VOC emissions were developed from Organic Profile No. 818 for diesel-fueled equipment, and Organic Profile No. 2110 for gasoline vehicles. TAC emission inventories for construction equipment PM emissions were developed from Profile No. 425 for diesel-fueled equipment, and Profile No. 420 for construction dust.

G.1.10 GREENHOUSE GASES EMISSIONS INVENTORY

In addition to criteria pollutant emissions, construction equipment is a source of greenhouse gas (GHG) emissions. The project-related construction sources for which GHG emissions were calculated are the same as those calculated for criteria pollutant emissions and include the following:

- Off-Road On-Site Equipment
- On-Road On-Site Equipment
- On-Road Off-Site Equipment

Data such as the project schedule, quantity data, construction equipment usage and construction activity, are used in the same way for developing the GHG emissions inventory as for the criteria pollutant inventory. Differences in methodology as to how applicable GHG emission factors are derived are described in this section.

Off-Road On-Site Equipment

In addition to criteria pollutants, OFFROAD2007 provides data for calculating emission factors for GHGs, including CO_2 and CH_4 . For off-road on-site equipment, these emission factors were derived and applied using the same methodology described in Section G.1.1 for CO and SO_x . For each equipment type, the appropriate emission factor for CH_4 was multiplied by its global warming potential (21) and added to the appropriate emission factor for CO_2 (with a global warming potential of 1) to calculate an emission factor of CO_{2e} in lb/hp-hr. This emission factor was then multiplied by equipment horsepower, load factor, an efficiency factor, and total operating hours, resulting in GHG emissions for the 2015 construction year.

On-Road On-Site Equipment

EMFAC2011 was used to obtain emission factors of CO_2 . These emission factors were obtained and applied using the same methodology described in Section G.1.2 for criteria pollutants. CO_2 emission factors obtained from EMFAC2011 and used in this analysis assume Pavley-I and Low Carbon Fuel Standard (LCFS) benefits.

In accordance with CARB guidance, for heavy-duty vehicles (assumed to be all on-road on-site vehicles except on-site pickup trucks) emission factors for CH₄ were calculated by multiplying the TOG emission factor by

0.0408. N_2O emission factors for all on-road on-site diesel vehicles were calculated by applying a factor of 0.3316 grams/gallon of fuel consumed by the vehicles. EMFAC2011 was used to derive the gallons of fuel consumed per VMT for T7 single construction vehicles by year. The resulting fuel consumption was multiplied by the grams/gallon factor above to derive an emission factor of N_2O in g/mi. This emission factor was then multiplied by an assumed on-site speed of 20 mph, resulting in an emission factor in g/hr.

For on-road on-site gasoline vehicles (i.e., on-site pickup trucks), EMFAC2011-LDV was used to calculate CH4 emission factors in g/mi and multiplied by an assumed speed of 20 mph to derive emission factors in g/hr. Per CARB guidance, N₂O emission factors for gasoline vehicles were derived by multiplying the appropriate NO_x emission factor (in g/hr) by 4.16 percent.

Once appropriate emission factors for CO_2 , CH_4 , and N_2O were calculated for each vehicle, a combined emission factor of CO_{2e} was derived by taking the sum of the emission factor of CO_2 (multiplied by a global warming potential of 1), the emission factor for CH_4 (multiplied by a global warming potential of 21) and the emission factor for N_2O (multiplied by a global warming potential of 310). The resulting emission factor of CO_{2e} in g/hr was converted to lb/hr, which was applied to the monthly operating hours for each equipment type to estimate monthly emissions.

On-Road Off-Site Equipment

GHG emission factors and resulting emissions for on-road off-site vehicles were obtained and applied using the same methodology described in Section G.1.3 for criteria pollutants. Emission factors of CO_{2e} for on-road off-site equipment were calculated using the same methodology described previously for on-road on-site equipment, except that emission factors were derived in lb/mi and multiplied by the annual operating hours for each equipment type to estimate monthly emissions.

Greenhouse Gases Emissions Summary

Table G-10 summarizes the total emissions of CO_{2e} generated by the Proposed Action Alternative by each construction sector. Results are shown in metric tons of CO_{2e} .

G.2 Operational Emissions Analysis

Operational emissions associated with the Proposed Action were calculated using the FAA's Emissions and Dispersion Modeling System (EDMS) Version 5.1.4.1. EDMS is a combined emissions and dispersion model developed by the FAA. EDMS is the FAA's and EPA's preferred guideline model for air quality analyses at airports. The primary applications of the model are to generate an inventory of emissions caused by sources on and around an airport and to calculate pollutant concentrations in the surrounding environment. EDMS data tables include emission factors for civilian and military aircraft, ground support equipment, and motor vehicles. EDMS criteria pollutant emissions inventories include CO, VOC, NO_X, SO_X, PM₁₀, and PM_{2.5}. While the EDMS emissions inventory module incorporates EPA-approved methodologies for calculating aircraft emissions were calculated in this EA. The Proposed Action Alternative does not alter aircraft takeoff or landing points, auxiliary power units (APUs), ground support equipment (GSE), or on-road mobile sources.

Annual aircraft emissions are a function of the number of annual operations, the aircraft fleet mix (types of aircraft/engines used), the length of time aircraft spend in various modes (taxi/idle, takeoff, climbout, approach, and landing roll), and the emission rates of the engine. The EDMS database contains an expansive list of aircraft types (airframes) and engine types for use in air quality analyses.

G.2.1 ANNUAL OPERATIONS AND FLEET MIX

Annual landing and takeoff (LTO) cycles data were assembled to determine existing and projected pollutant emissions from aircraft operations. LTO cycles are one-half the number of total aircraft operations, because one aircraft operation represents one takeoff or landing. Annual 2012 operations are shown in **Table G-11**. Aircraft engines representing the actual in-use fleet at LAX were applied in EDMS using LAWA's Aircraft Noise and Operations Monitoring System (ANOMS) data, and cross-referenced with proprietary fleet data for air carrier and business jet operations, on the basis of reported aircraft tail number. In segments of the fleet where such matches were not possible, EDMS default engine selections were retained.

 LAX 2012 Annual Operations and Fleet Mix (3 of 3)

SOURCE: Ricondo & Associates, Inc., January 2014.

PREPARED BY: Ricondo & Associates, Inc., January 2014.

Annual aircraft operations were developed based on the No Action Alternative and Proposed Action aircraft operations forecasts for 2015, as depicted in **Table G-12**. As the number and types of airport operations do not change under the Proposed Action Alternative, the fleet mix is the same as the No Action Alternative.

 Table G-13
 2020 Annual Operations and Fleet Mix (3 of 3)

SOURCE: URS Corporation, 2013.

PREPARED BY: Ricondo & Associates, Inc., January 2014.

G.2.2 AIRCRAFT TIME IN MODE

To model aircraft emissions, it is necessary to determine the time for each of the five operating modes that make up an LTO cycle – approach, taxi-in, taxi-out, takeoff, and climbout. To derive times spent in the approach, takeoff, and climbout modes, EDMS uses a dynamic flight performance modeling module that

accounts for aircraft weight and meteorological conditions. Mixing heights at LAX are adjusted to 1,806 feet. To obtain taxi-in and taxi-out times, SIMMOD was used, as discussed in Section G.1.7, *Aircraft Operations during Construction*. SIMMOD of aircraft operations for the 2015 No Action and Proposed Action Alternatives were developed in order to determine Project-specific taxi/idle times. Aircraft emissions were then calculated using EDMS and the taxi/idle times derived from the SIMMOD results.

Taxi times for the 2015 No Action and Proposed Action Alternatives were calculated based on the difference of the averages of the following runway operating conditions from SIMMOD:

- Visual flight rules (VFR) with visual approaches West Flow (69.2%); and
- VFR with simultaneous instrument landing system (ILS) approaches West Flow (24.6%)

These configurations make up nearly 94 percent of the runway operating configurations at LAX, as shown in **Table G-14**.

| Table G- | 14 LAX Primary Ru | nway Operating Configura |
|---|--------------------|--------------------------|
| C | ONFIGURATION | ANNUAL USE |
| VFR | Visual - West Flow | 69.2% |
| VF | R ILS – West Flow | 24.6% |
| VF | R ILS – East Flow | 2.1% |
|] | FR – West Flow | 4.1% |

PREPARED BY: Ricondo & Associates, Inc., January 2014.

Table G-15 depicts the total aircraft operations utilized in the emissions inventories for the 2015 and 2020 calendar years. These operational levels do not differ between the No Action Alternative and the Proposed Action for a given year, and are based upon total operations reported in the FAA Terminal Area Forecast (TAF) and extrapolated annual operations based on the Specific Plan Amendment Study (SPAS) Passenger Forecast. Table G-15 also presents the SIMMOD derived taxi times utilized in the operational emissions analysis by year and alternative. There would be no difference in taxi times between the No Action Alternative and the Proposed Action for either 2015 or 2020. As mentioned above, these are average taxi times based on two of the primary runway operating configurations; they include unimpeded taxi time and ground delay.

| | | TAXI-IN TIM | E (MINUTES) | TAXI-OUT TIN | /IE (MINUTES) |
|------|------------|-------------|--------------------|--------------|--------------------|
| YEAR | OPERATIONS | NO ACTION | PROPOSED ACTION | NO ACTION | PROPOSED ACTION |
| 2015 | 618,978 1/ | 9.21 | 9.21 | 12.05 | 12.05 |
| 2020 | 705,281 2/ | 10.90 | 10.90 | 13.82 | 13.82 |

NOTES:

1/ The 2015 annual operations were extrapolated based on the numbers of forecasted passengers identified in the SPAS Passenger Forecast, a peak monthto-year ratio for July 2012 and the resulting numbers of peak month average day operations for each year between 2009 and 2025.

2/ The 2020 annual operations were obtained from the 2012 Federal Aviation Administration Terminal Area Forecast for 2020.

SOURCE: Ricondo & Associates, Inc., January 2014.

PREPARED BY: Ricondo & Associates, Inc., January 2014.

Annual emissions were calculated in EDMS using the above fleet mixes and times in mode.

G.2.3 HAZARDOUS AIR POLLUTANTS

In addition to criteria pollutants, EDMS also provides HAP emissions for certain pollutants associated with aircraft operations, mainly from formaldehyde, acetaldehyde, acrolein and propylene. Inputs into EDMS were the same as those outlined in Sections G.2.1 and G.2.2 for criteria pollutants.

G.2.4 GREENHOUSE GAS EMISSIONS

Parts of the earth's atmosphere act as an insulating blanket, trapping sufficient solar energy to keep the global average temperature in a suitable range. The blanket is a collection of atmospheric gases called GHGs. These gases – primarily water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), ozone, chlorofluorocarbons (CFCs), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6) – all act as effective global insulators, reflecting back to earth visible light and infrared radiation.

The global warming potential (GWP) is the potential of a gas or aerosol to trap heat in the atmosphere; it is the "cumulative radiative forcing effects of a gas over a specified time horizon resulting from the emission of a unit mass of gas relative to a reference gas." Individual GHG species have varying GWP and atmospheric lifetimes. The carbon dioxide equivalent (CO₂e) -- the mass emissions of an individual GHG multiplied by its GWP is a consistent methodology for comparing GHG emissions because it normalizes various GHG emissions to a consistent metric. The three GHGs focused on in this Environmental Assessment are CO₂, CH₄, and N₂O. The reference gas for GWP is CO₂; CO₂ has a GWP of 1. Compared to CH₄'s GWP of 21, CH₄ has a greater global warming effect than CO₂ on a molecule-per-molecule basis. N₂O has a GWP of 310.

In addition to criteria pollutants and HAPs emissions, EDMS also provides aircraft CO_2 emissions. Inputs into EDMS were the same as those outlined in Sections G.2.1 and G.2.2 for criteria pollutants. CH_4 and N_2O emissions are not directly estimated by EDMS; therefore, it was necessary to estimate emissions using other methods. Emissions were calculated using fuel burn (converted from lbs to gallons) from EDMS and emission

factors (in g/gal of fuel) from the U.S. Energy Information Administration. Emission factors for CH_4 and N_2O are shown in **Table G-16**. Once appropriate emissions for CH_4 and N_2O were calculated, MTCO₂e was calculated by taking the sum of CO_2 emissions (multiplied by a global warming potential of 1), the CH_4 emissions (multiplied by a global warming potential of 21) and the N_2O emissions (multiplied by a global warming potential of 310).

| Table G-16 Jet Fuel GHG Emission Factors | | |
|--|------------------|------------------|
| FUEL TYPE | CH4 (G/GAL FUEL) | N2O (G/GAL FUEL) |
| Jet Fuel | 0.27 | 0.31 |
